Dipoles in the sky

Dragan Huterer

Physics Department University of Michigan

Work with Cameron Gibelyou (Michigan PhD April 2012)

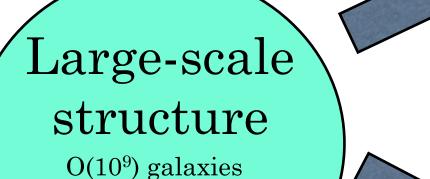

Organization of talk

- 1. Special advertising section: fundamental physics with LSS
- 2. Overview of large-angle CMB anomalies...
- 3. ... and how to test them using LSS
- 4. Constraints on dipole(s) from the LSS

Fundamental Physics from LSS

- Amount, clustering of Cold Dark Matter
- Expansion history (⇔dark energy)
- Modified Gravity (⇔dark energy)
- Self-interactions of dark matter
- Neutrino masses ($\sum m_v \le 0.3 \text{ eV}$)
- Features in inflationary potential
- Primordial non-Gaussianity of density perturbations
- Statistical isotropy of the universe

 $O(10^7)$ with spectra

 $O(10^6)$ quasars

 $O(10^5)$ clusters

"Astrophysics":

- galaxy formation
- dust
- baryonic (nonlin) physics
- star formation

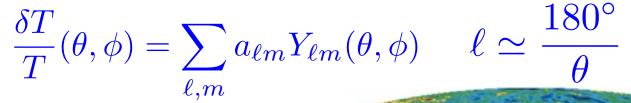

-

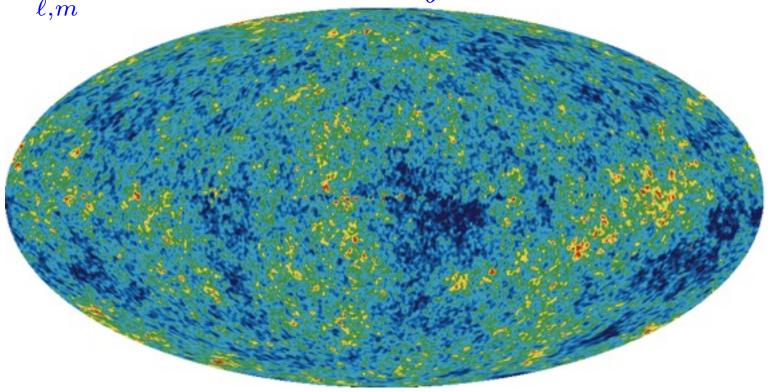

Systematics

"Cosmology":

- dark energy
- dark matter
- neutrino masses
- non-Gaussianity
- statistical isotropy
- cosmic strings

Initial conditions in the universe

$$\langle a_{\ell m} \, a_{\ell' m'} \rangle \equiv C_{\ell \ell' m m'} = C_{\ell} \delta_{\ell \ell'} \delta_{m m'}$$

Gaussianity:
$$\langle a_{\ell m} \, a_{\ell' m'} \, a_{\ell'' m''} \rangle = 0$$

Statistical Isotropy simplified:

T = fluctuating field on the sky

Statistically Isotropic: $\langle T(\hat{\mathbf{n}})T(\hat{\mathbf{n}}')\rangle = C(\hat{\mathbf{n}}\cdot\hat{\mathbf{n}}')$

NOT Stat. Isotropic: $\langle T(\hat{\mathbf{n}})T(\hat{\mathbf{n}}')\rangle = C(\hat{\mathbf{n}},\hat{\mathbf{n}}')$

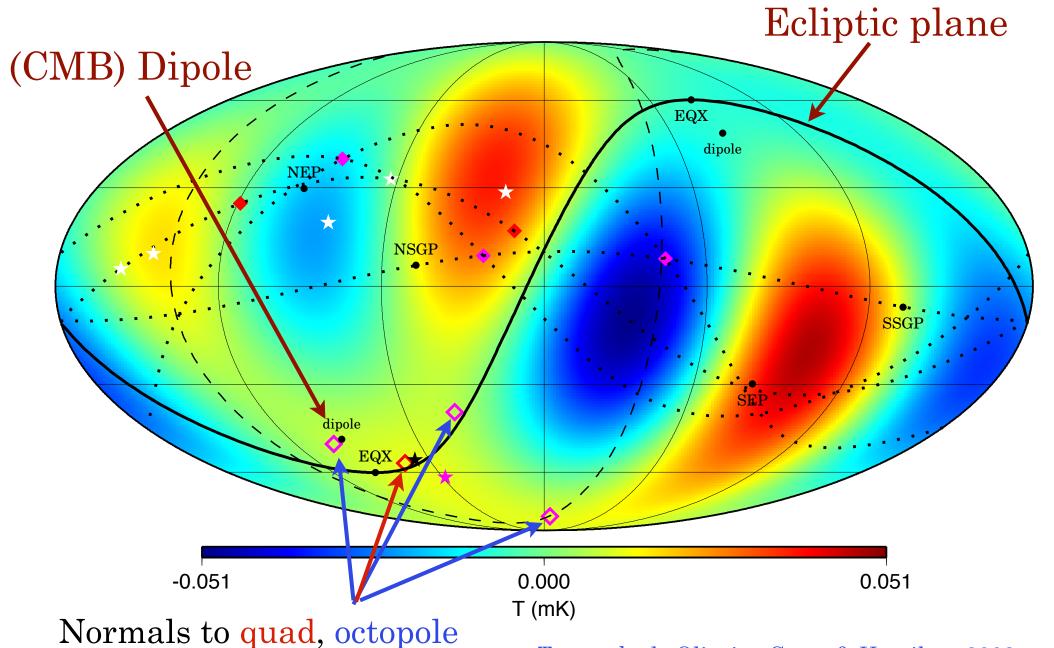

same as

 $\langle a_{\ell m} \, a_{\ell' m'} \rangle \equiv C_{\ell \ell' m m'} = C_{\ell} \delta_{\ell \ell'} \delta_{m m'}$

Assuming SI, we get most results in cosmology (e.g. average $2\ell+1$) modes for each ℓ across the sky

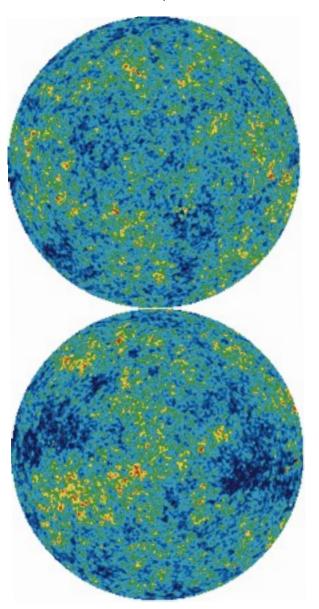

CMB large-angle "anomalies"

L=2+3 alignments

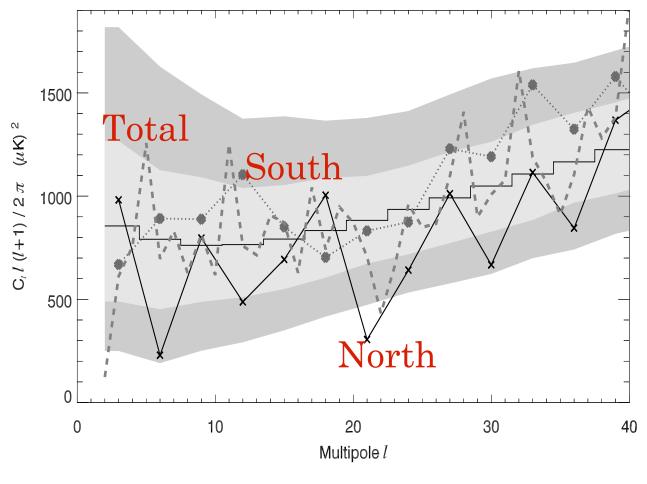

Tegmark, de Oliveira-Costa & Hamilton 2003 Schwarz, Starkman, Huterer & Copi 2004, 06, 10

N/S power asymmetry ("hemispherical anomaly")

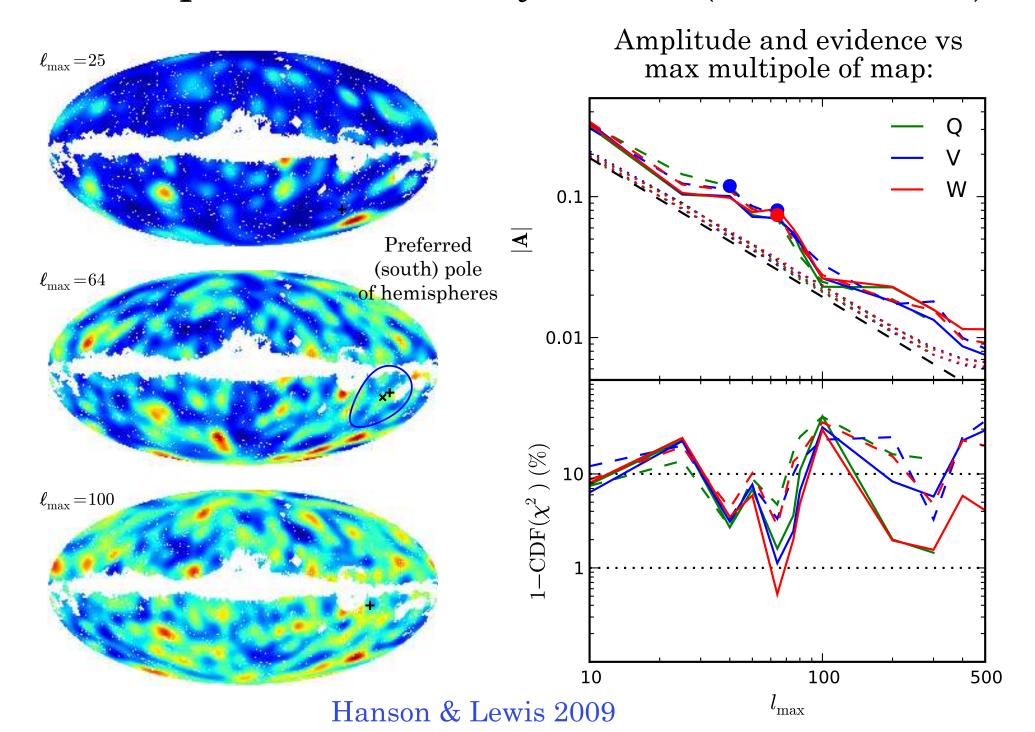

South (ecliptic) has more power than north

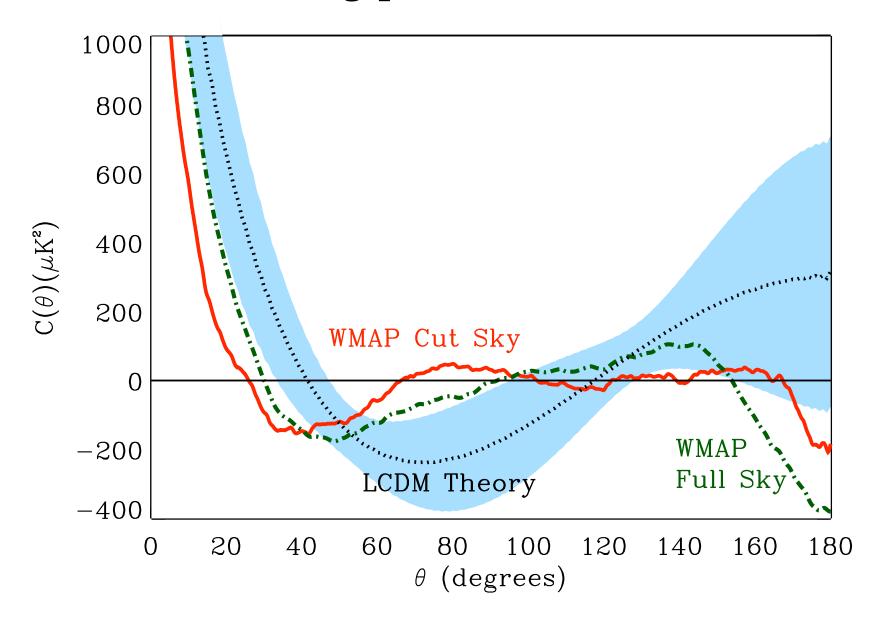

Eriksen et al 2004; Hansen, Banday and Gorski 2004

Hemispherical anomaly: latest (from WMAP)

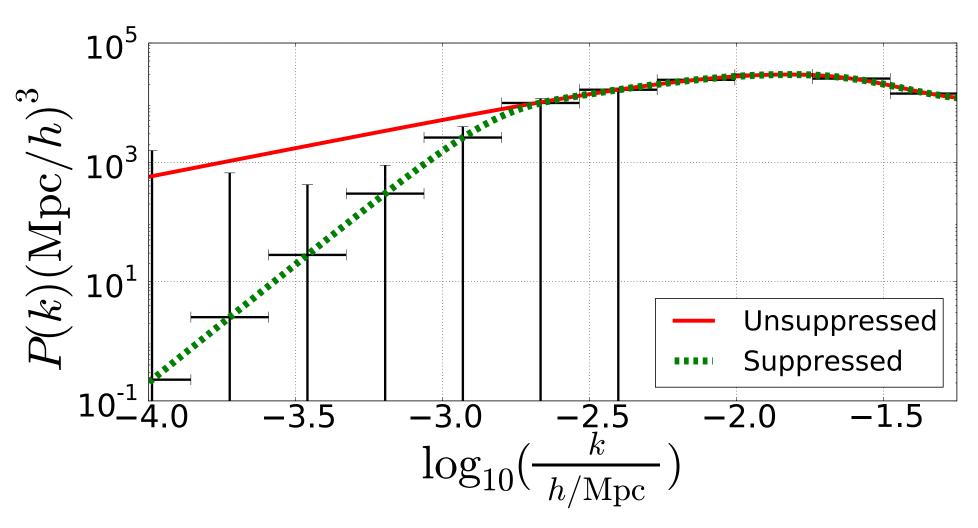

Missing power above 60°

Hinshaw et al 1996 (COBE); Spergel et al 2003 (WMAP) Copi et al 2007, 2009; Sarkar et al 2010

Using LSS to test whether low P(k) is the cause of low $C(\theta)$

Can do this with LSS if you have a HUGE number of galaxy redshifts, as assumed in plot above (LSST with gazillion redshifts)

Gibelyou, Huterer & Fang 2010

Dipoles

Kinematic and Intrinsic Dipoles in CMB and LSS

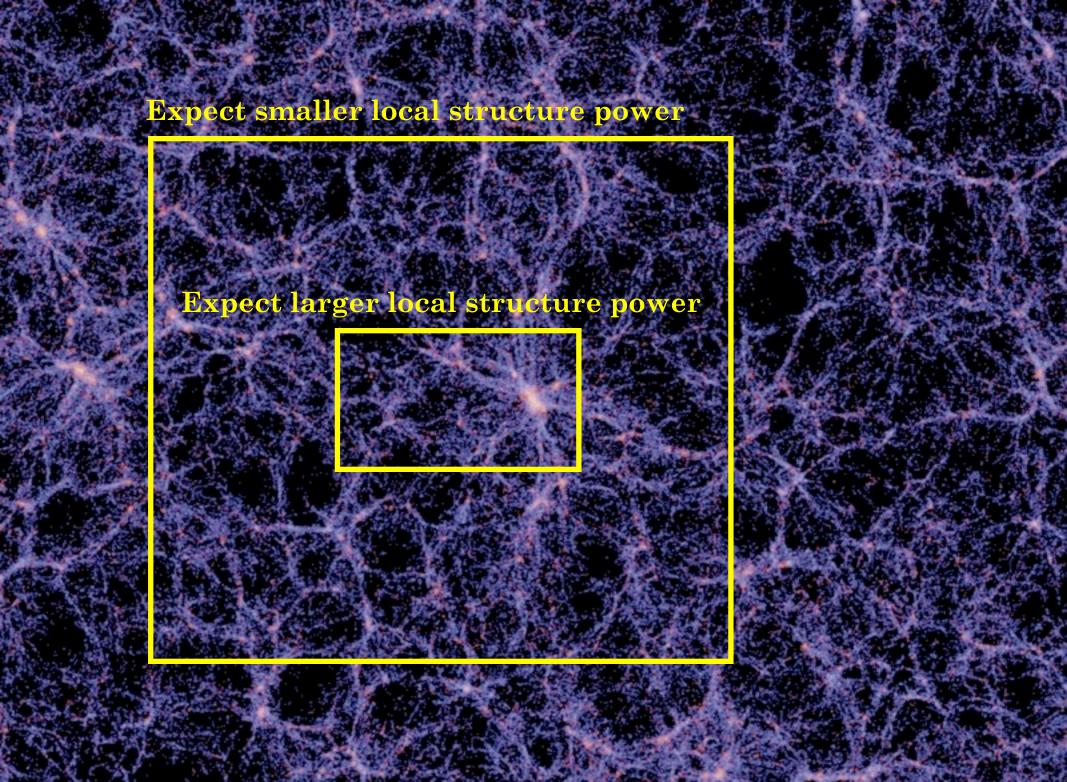

Nomenclature:

- Local structure dipole: due to finite volume, we are looking 'along a filament' of LSS
- ▶ Kinematic dipole: due to our motion wrt the CMB or LSS
- ▶ Intrinsic dipole: primordial origin

Type of Dipole	Expected Value in CMB	Expected Value in LSS
kinematic	$\sim v/c \sim 10^{-3}$	$\sim v/c \sim 10^{-3}$
intrinsic	$\sim 10^{-5}$	$\sim 10^{-5} - 1$

Kinematic Dipole: vital statistics

- Earth around Sun: speed ~ **30 km/s**, direction annually varying (Blake & Wall, 2002); values of CMB dipole are cited with this subtracted out, so that dipole is due only to Sun's velocity wrt CMB
- Sun around Galaxy: speed ~ **220 km/s** (or more precisely, Sun with respect to Local Standard of Rest, and LSR with respect to Milky Way (Itoh, Yahata, Takada, 2010), direction (l,b) = (90,0) (Courteau and van den Bergh, 1999)
- Sun with respect to the Local Group: speed ~ **306 km/s**, direction (l,b) = (99, -4) +/- (5, 4) (Courteau and van den Bergh, 1999; see their Table 2 for historical details)
- Local Group with respect to CMB (peculiar velocity): speed \sim **622 km/s**, direction (l,b) = (272, 28) (Maller et al., 2003, computed using Courteau and van den Bergh's value for Sun wrt LG) (peculiar velocity predicted from linear-theory LCDM \sim 470 km/s)
- Overall CMB kinematic dipole: speed ~ **370 km/s**, direction (l,b) = (264.4, 48.4) (Kogut et al., 1993) (note that the speed would be higher if not for the fact that the above two vectors point in near-opposite directions)

Theoretical prediction for angular power spectrum

$$C_{\ell} = 4\pi \int_0^{\infty} d\ln k \, \Delta^2 \left(k, z = 0 \right) I^2(k)$$

where

$$I(k) \equiv \int_0^\infty dz \, W(z) \frac{D(z)}{D(0)} \, j_\ell(k\chi(z))$$

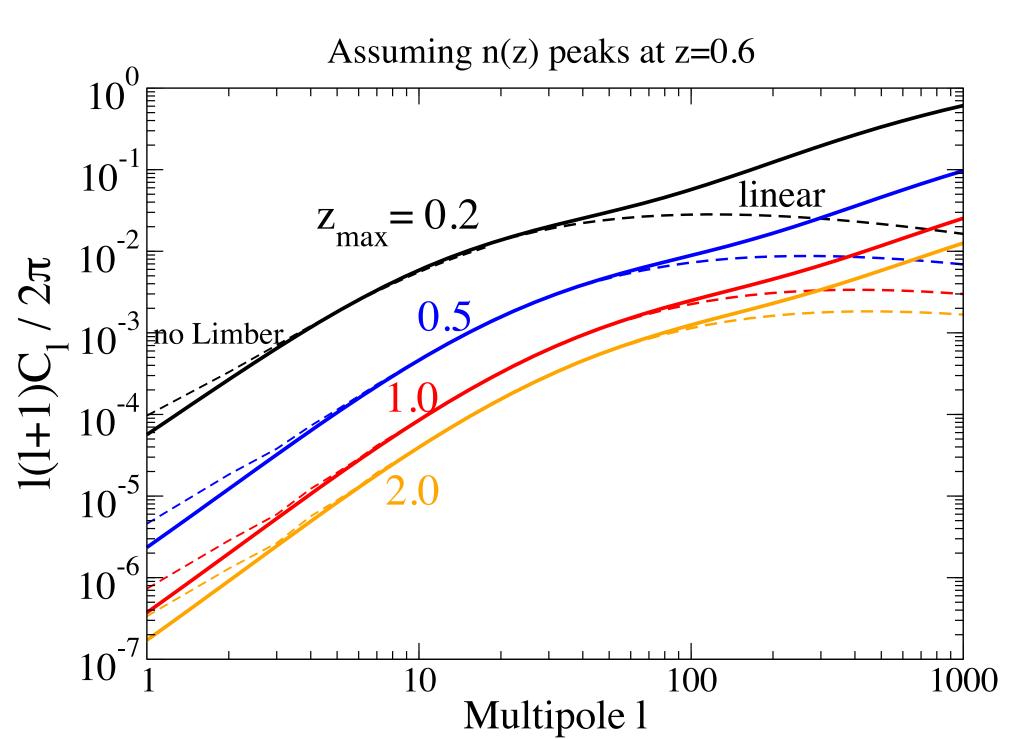

$$W(z) = \frac{b(z)N(z)}{\int_{z_{\min}}^{z_{\max}} N(z)dz}$$

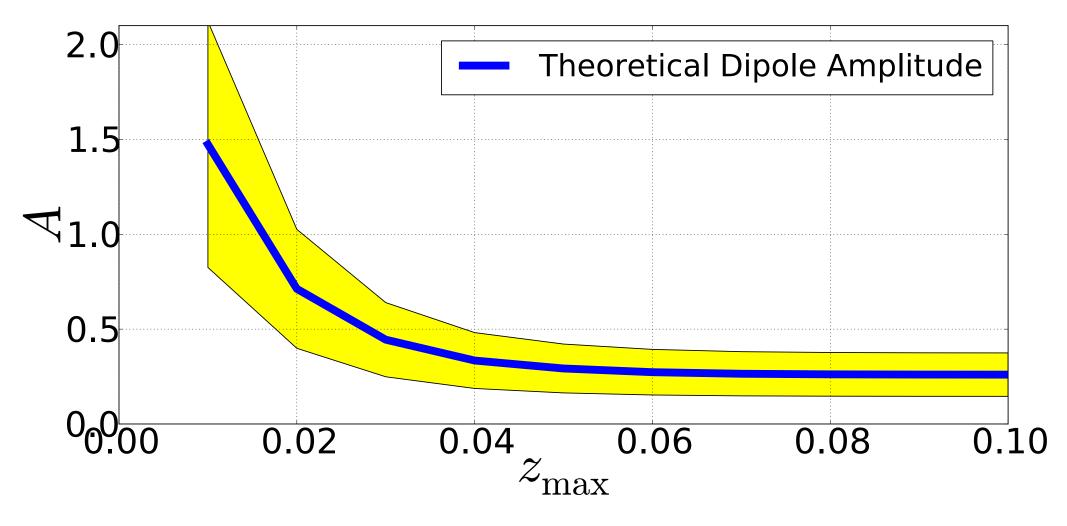

Note in particular:
$$N(\hat{\mathbf{n}}) = \bar{N}(\hat{\mathbf{n}}) \left[1 + A \left(\hat{\mathbf{d}} \cdot \hat{\mathbf{n}} \right) \right]$$

$$C_1 \equiv \frac{4\pi}{9}A^2 = \text{dipole power}$$

$$\sigma(C_{\ell}) = \sqrt{\frac{2}{(2\ell+1) f_{\rm sky}}} C_{\ell} = \text{cosmic variance error}$$

Expected power spectrum of LSS

(not actually converging in this plot since there we run out of fewer galaxies at higher z in this sample)

In literature, usually: flux-weighted dipole

$$\mathbf{v} = \frac{2f(\Omega_M)}{3H_0\Omega_M} \mathbf{g}$$

$$\mathbf{g}(\mathbf{r}) = \frac{G}{b} \int \rho_g(\mathbf{r}') \frac{\mathbf{r}' - \mathbf{r}}{|\mathbf{r}' - \mathbf{r}|^3} d^3 \mathbf{r}' = \frac{G}{b} \sum_i M_i \frac{\hat{\mathbf{r}}_i}{r_i^2}$$

$$= \frac{4\pi G}{b} \sum_i \frac{M_i}{L_i} \frac{L_i}{4\pi r_i^2} \hat{\mathbf{r}}_i = \frac{4\pi G}{b} \sum_i \frac{M_i}{L_i} \frac{S_i}{r_i},$$

Assume M/L is constant, weigh galaxies with measured flux S_i to get \boldsymbol{g}

Why you might not get convergence to the kinematic dipole...

Long-wavelength perturbations

Grischuk & Zeldovich 1978
Turner 1991
Gordon, Hu, Huterer, & Crawford 2005
Erickcek, Carroll & Kamionkowski 2008

• Isocurvature perturbations

Erickcek, Kamionkowski & Carroll 2008

• Bubble collisions (but tiny effect?)

Johnson et al., Kleban et al...

• ...

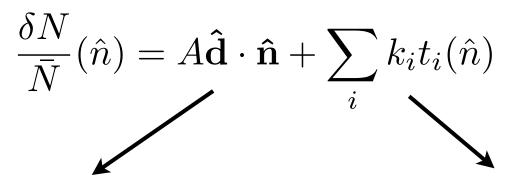

This work: looking at the number density of galaxies in different directions

Relativistic aberration: galaxies "bunch up" in direction of motion

 $n(\theta, \phi) \rightarrow n(\theta, \phi) [1+2\beta \cos \alpha]$

Methodology

Hirata 2009

Dipole modulation of number counts

Systematics templates (k_i is amplitude)

Motivated by similar models suggested in context of the CMB, e.g.

$$T_{\text{obs}}(\hat{\mathbf{n}}) = T(\hat{\mathbf{n}}) [1 + w(\hat{\mathbf{n}})]$$

Gordon, Hu, Huterer, Crawford 2005

$$P_{\text{obs}}(\mathbf{k}) = P(k) \left[1 + w(\hat{\mathbf{k}}) \right]$$

Ackerman, Carroll & Wise 2007 Pullen & Kamionkiwski 2009

Solution and an estimator:

Hirata 2009

$$\hat{\mathbf{x}} = F^{-1}g$$

$$g_i = \sum_D T_i(\hat{n}_D) - \frac{N_D}{N_R} \sum_R T_i(\hat{n}_R)$$

$$F_{ij} = \frac{N_D}{N_R} \sum_R T_i(\hat{n}_R) T_j(\hat{n}_R)$$

[where
$$\mathbf{x} = (d_x, d_y, d_z, k_1, ...k_N, C)$$
]

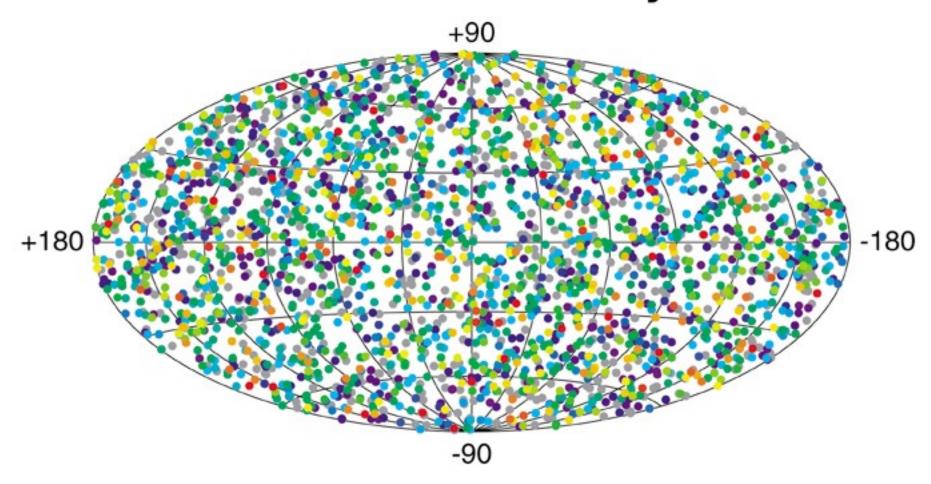

If you want just amplitude marginalized over direction, that's easy too:

$$\mathcal{L}(A) \propto \int \exp \left[-\frac{1}{2} (A\hat{d} - d_{\text{best}}) \text{Cov}^{-1} (A\hat{d} - d_{\text{best}}) \right] d^2 \hat{d}$$

Surveys and and Results

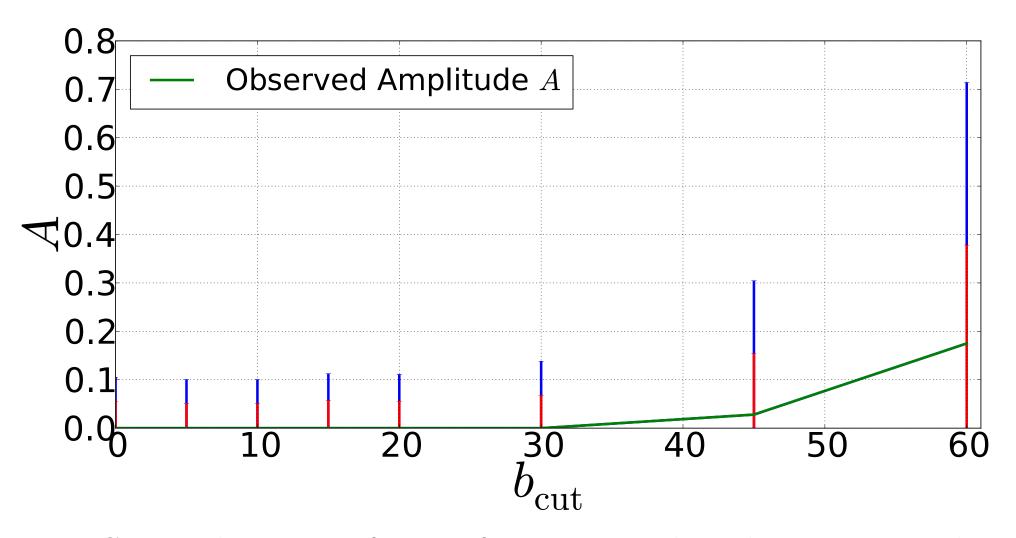

BATSE on Compton Gamma-Ray observatory

2704 BATSE Gamma-Ray Bursts

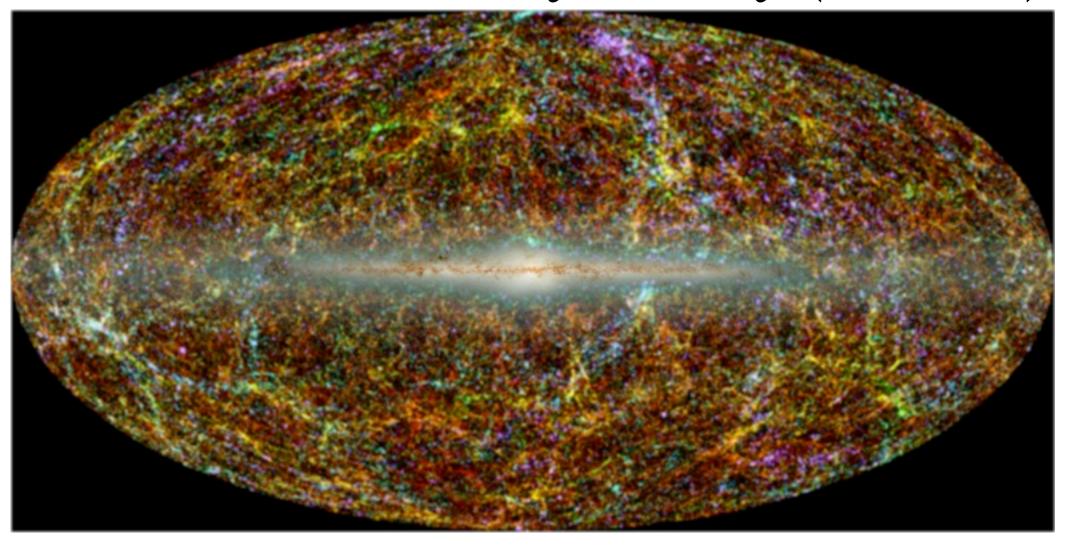

Transparent to structure in our Galaxy!

Theory vs. Observation, BATSE GRBs

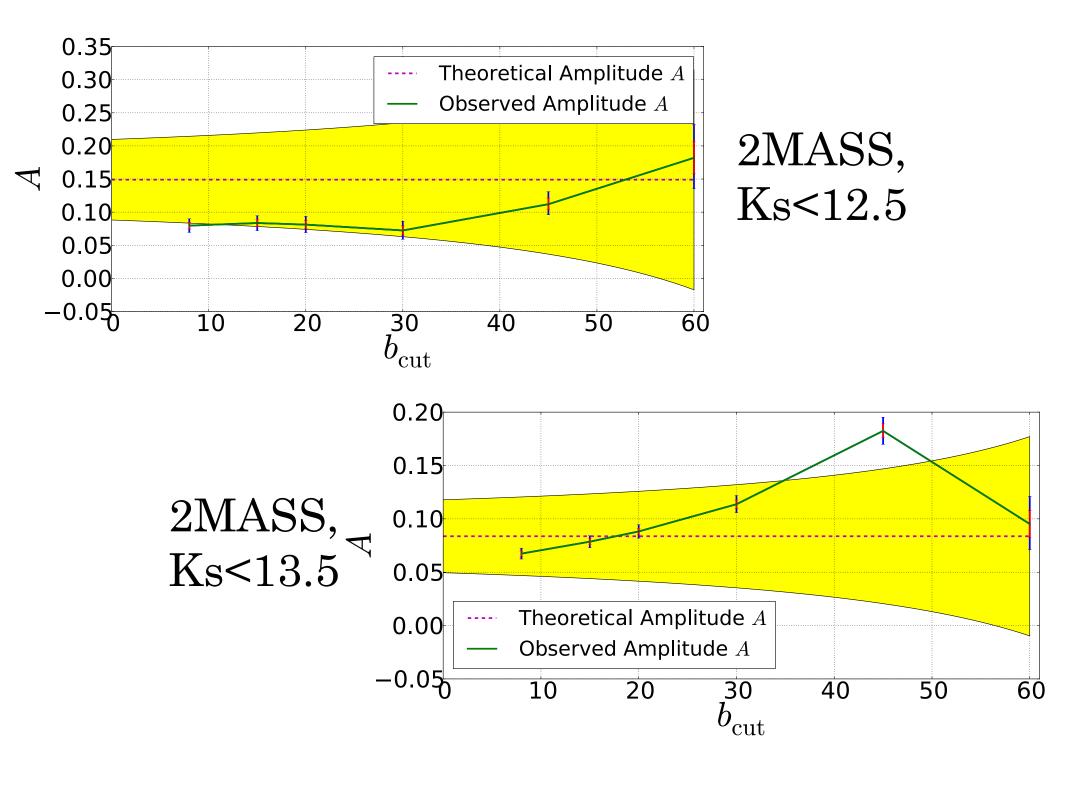

Constraints are a factor of ~10 too weak to detect expected dipole A=O(0.01) due to small density of GRBs, but this still presents a useful check

Two Micron All Sky Survey (2MASS)

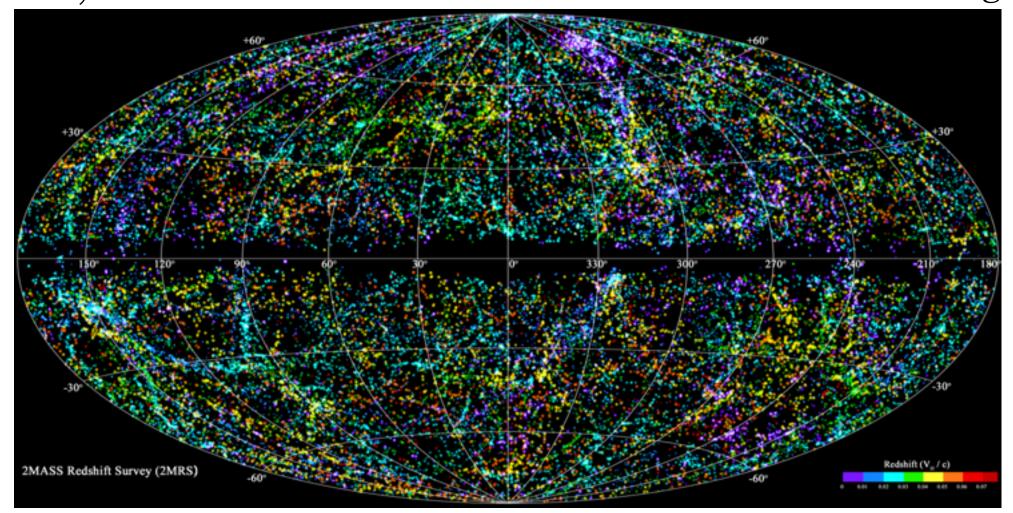

- ▶ Imaged 99.998% of sky at 1.25, 1.65 and 2.16 microns
- ▶ Extended Source Catalog: about 1.6 million extragalactic sources
- ▶ Mean redshift 0.05-0.07, depending on the cut (fainter \Rightarrow deeper)

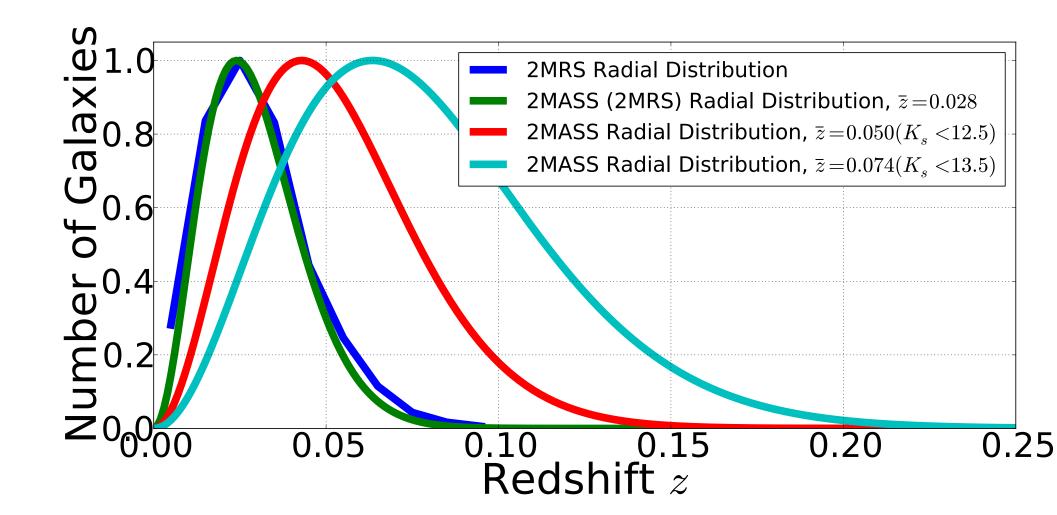

2MASS Redshift Survey (2MRS)

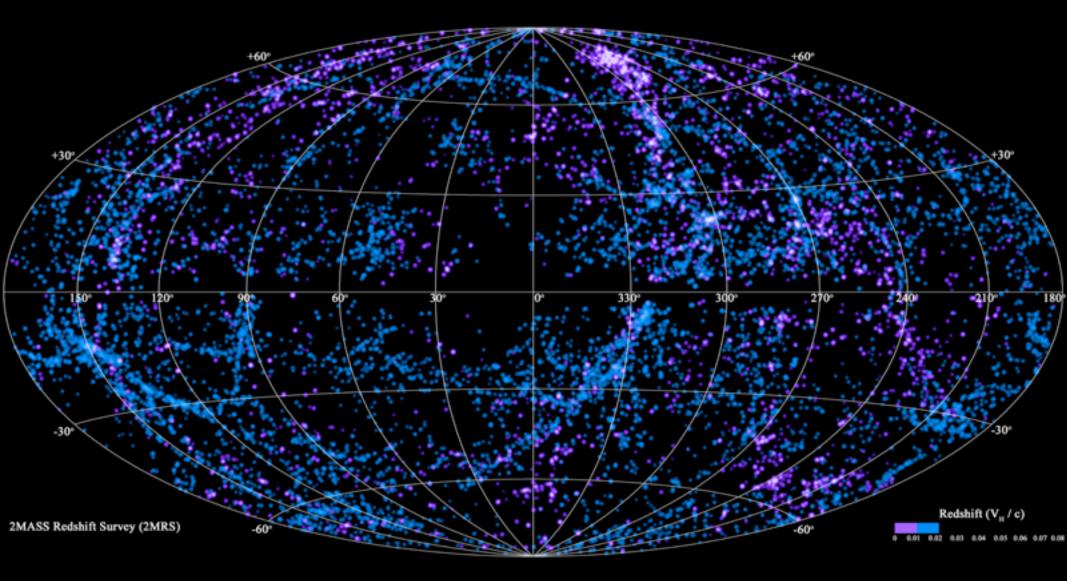

>40,000 redshifts

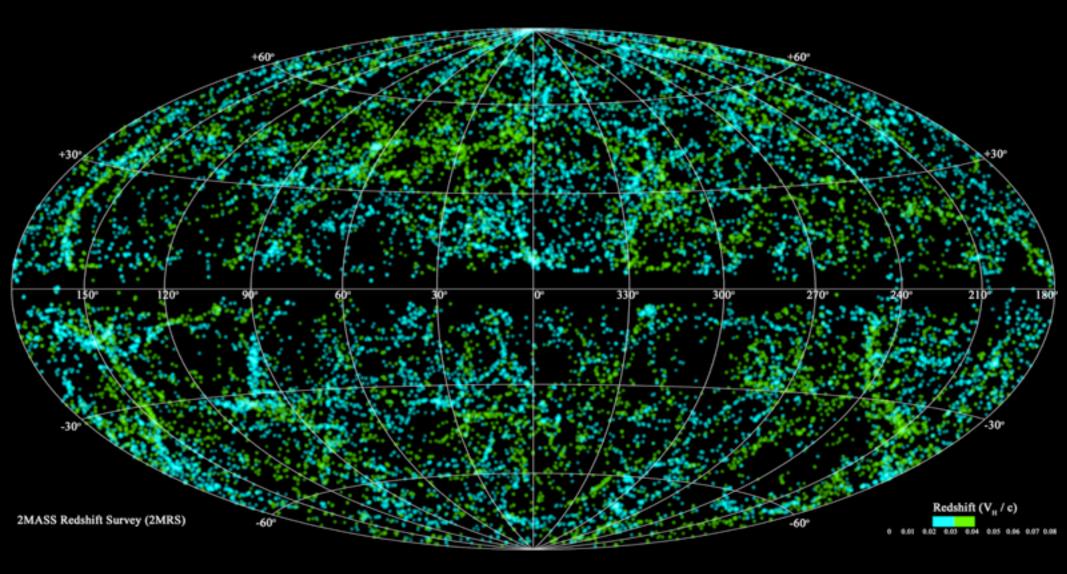

Ks < 11.75 mag

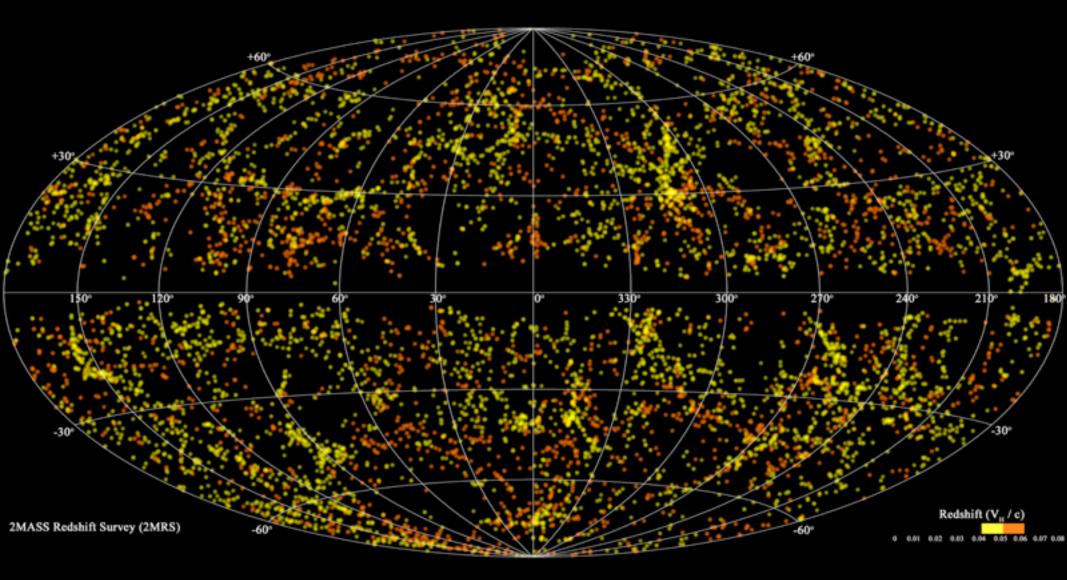

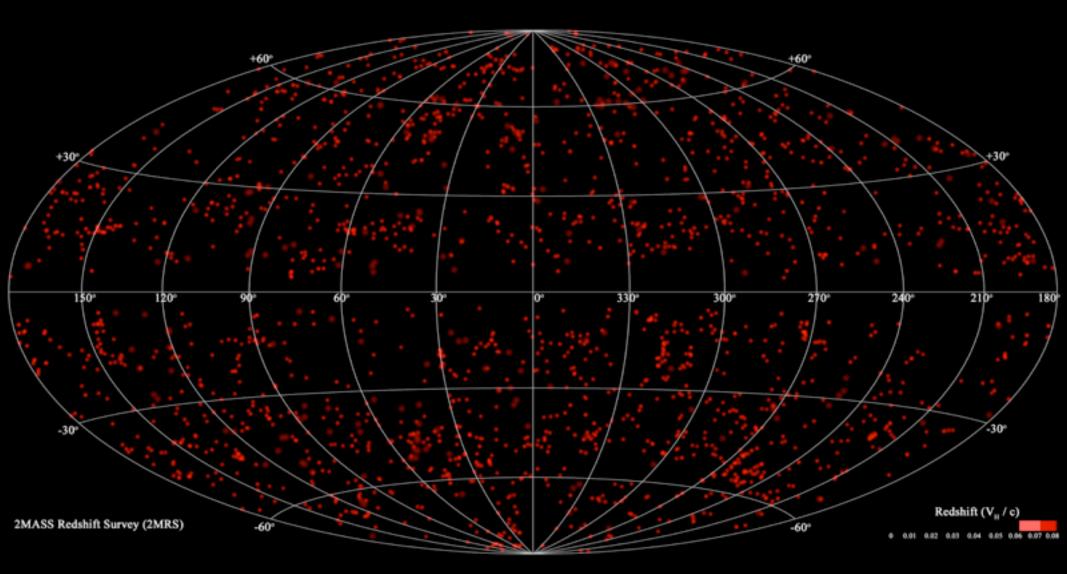

Huchra et al, arXiv:1108.0669

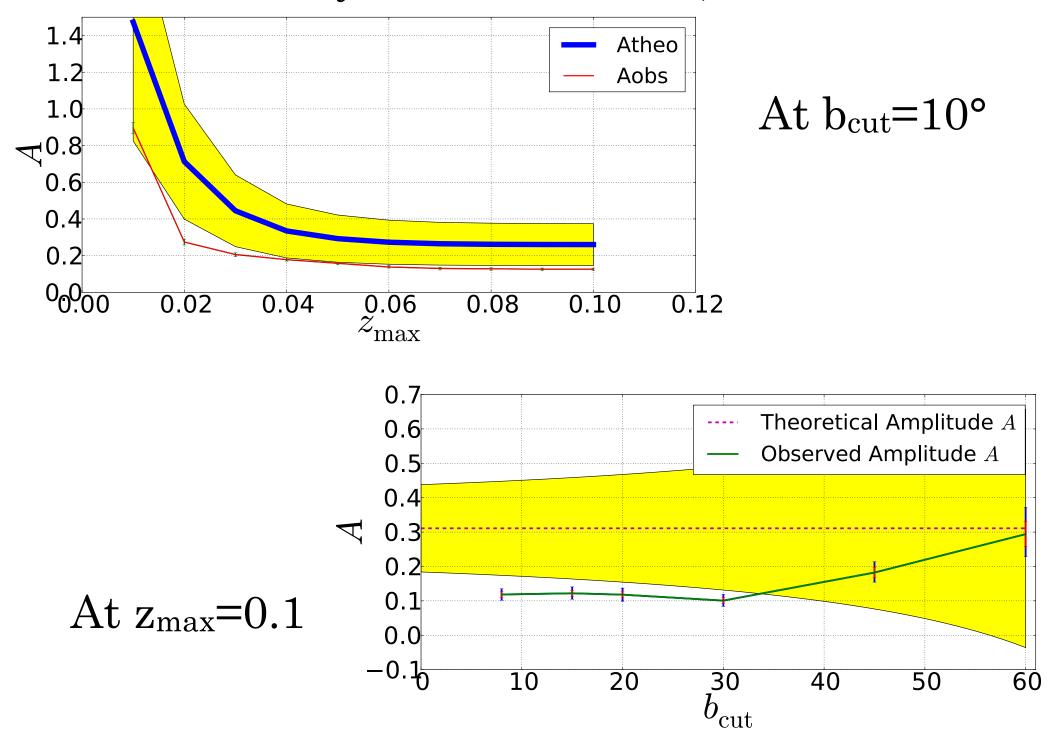

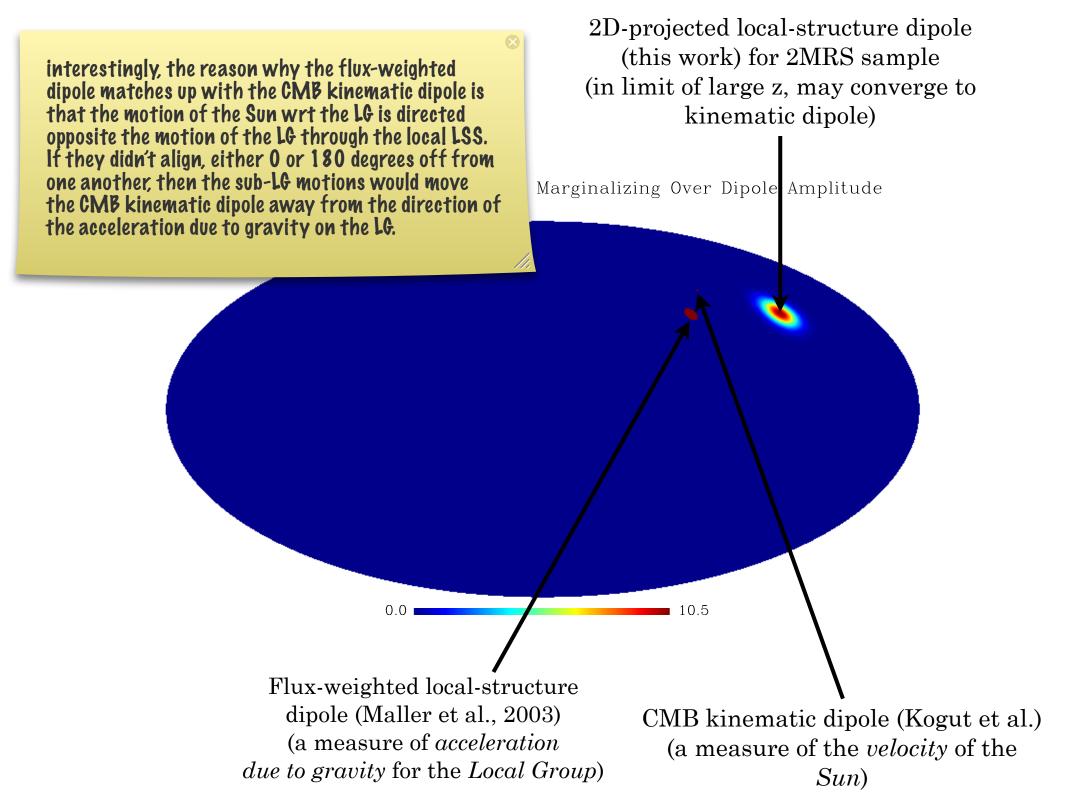

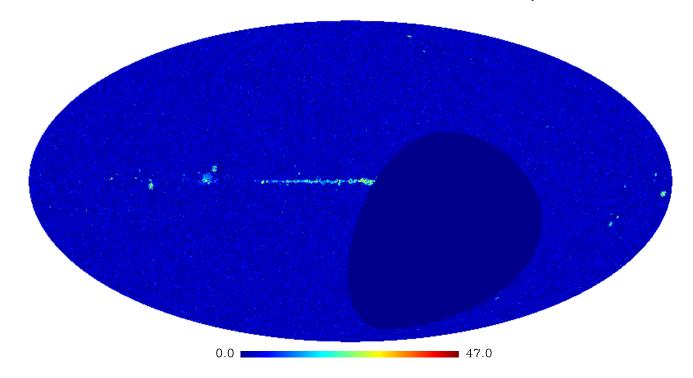

Theory vs. Observation, 2MRS

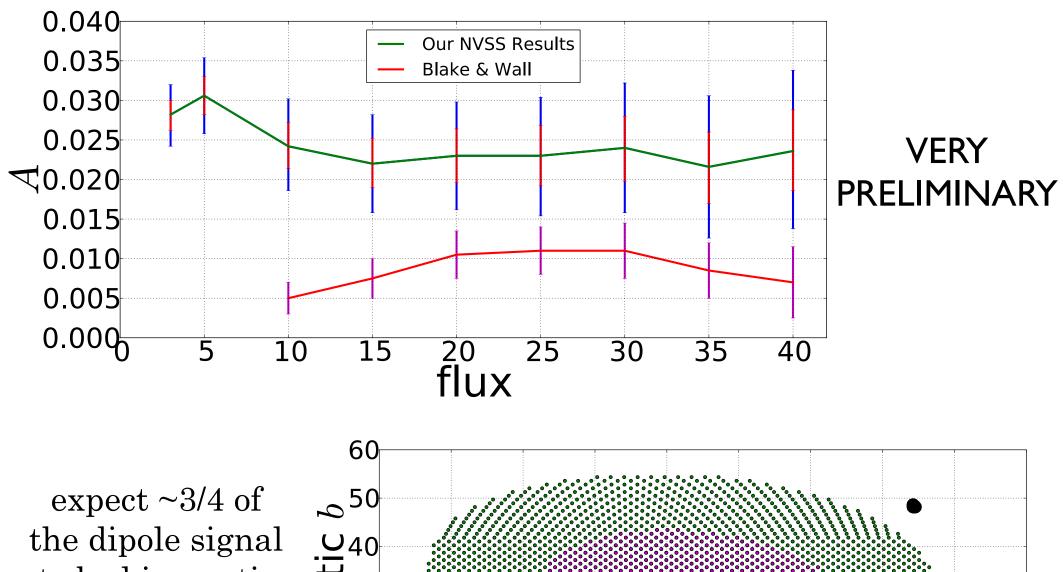

NRAO VLA Sky Survey (NVSS)

NVSS, Sources With Flux Greater Than 15 mJy

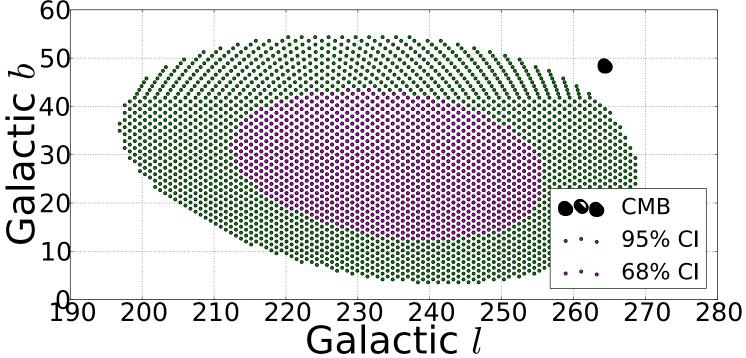

surveyed 82% of the sky at 1.4 GHz

1.8 million sources down to ~2.5 mJy; declination-dep. striping goes away for sources > 15 mJy

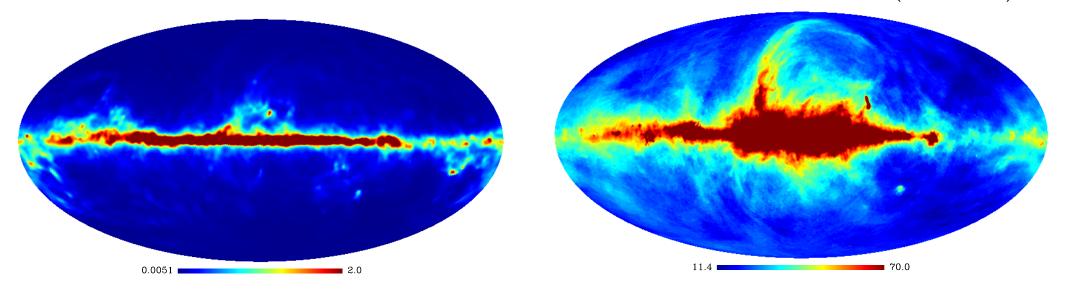

expect ~3/4 of the dipole signal to be kinematic in origin (so should match up with the CMB)

Systematics

Dust Emission/Extinction at 100 Microns

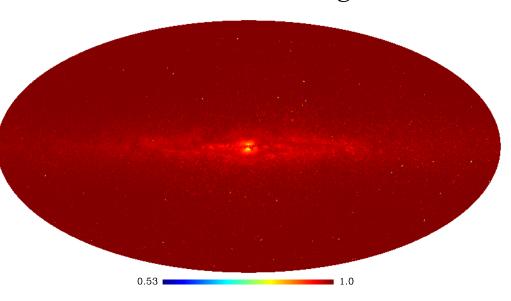

408 MHz Emission (Haslam)

BATSE Exposure Function

2MASS Coverage

Fundamental Physics from LSS

- Amount, clustering of Cold Dark Matter
- Expansion history (⇔dark energy)
- Modified Gravity (⇔dark energy)
- Self-interactions of dark matter
- Neutrino masses ($\sum m_v \le 0.3 \text{ eV}$)
- Features in inflationary potential
- Primordial non-Gaussianity of density perturbations
- Statistical isotropy of the universe

Conclusions

- LSS is a great tool to test fundamental physics beyond the cosmological parameters, for example statistical isotropy of the universe
- Comparison with CMB is particularly interesting. It tests longwavelength perturbations and other exotic physics (and models of inflation)
- So far, our (relatively modest) tests with LSS given results consistent with standard, statistically isotropic expectation
- With BOSS, DES, LSST, BigBOSS, Euclid, WFIRST, etc the LSS is entering a new era of precision tests => expect much better constraints of fundamental physics

EXTRA SLIDES

Directions

- CMB modulation: (I,b) = (224, -22) (Hoftuft et al.)
- CMB velocity dipole: (l,b) = (264.4, 48.4) +/- (0.3, 0.5) (Kogut et al., 1993) (Sun wrt CMB)
- Local Group velocity with respect to the CMB rest frame, inferred from CMB dipole measurement: (l,b) = (276,30) +/- (3,3) (Kogut et al., 1993)
- Local Group velocity with respect to the CMB rest frame, inferred from measurement of Sun's velocity wrt the LG: (l,b) = (272, 28) (Maller et al. 2003)
- Flux-weighted local-structure dipole from 2MASS: (I,b) = (278, 38)
 +/- (2.5, 2) (Maller et al., 2003)
- Local Group bulk flow: (I,b) = (258, 36) (Weyant, Wood-Vasey, Wasserman, and Freeman, 2011)

Relevant Scales for Convergence of Dipoles

- 40 Mpc/h ~ departure from linearity (Percival et al. 2001; see Frith, Outram, Shanks 2005)
- Blake & Wall (2002): IRAS dipole has converged by ~ 100 Mpc/h
- Maller et al. (2003): I50-200 Mpc/h

GRB-SGR confusion
