Anionic, hard base ligands, e.g.  $\text{SO}_4^{2-}$ ,  $\text{HPO}_4^{2-}$ ,  $\text{P}_2\text{O}_7^{4-}$ , are known to stabilize, via axial coordination, the Ni(III) complexes with tetraazamacrocyclic ligands, e.g. Ni(III)(cyclam), cyclam = 1,4,8,11-tetraazacyclotetradecane.  $\text{P}_2\text{O}_7^{4-}$  seems to be an optimal ligand and surprisingly electrochemical and pulse radiolysis experiments even suggest that  $\text{Ni}^{\text{IV}}\text{L}(\text{P}_2\text{O}_7)^{4-4n}$  ( $n = 1$  or  $2$ ) can be formed but is short lived. These results suggest that ATP might also form the complex  $\text{Ni}^{\text{III}}\text{L}(\text{ATP})_2^{5-}$ . Indeed the stability constant for the binding of ATP to  $\text{Ni}^{\text{III}}\text{L}(\text{H}_2\text{O})_2^{3+}$  is found to be  $K_{\text{eq}} = 1.2 \times 10^{11} \text{ M}^{-2}$ ,  $E_{1/2} = 0.41 \text{ V}$  for the  $\text{Ni}^{\text{III/II}}\text{L}$  couple in solutions containing 0.016M ATP at pH 7.0. This complex is stable in aerated solutions. However the electrochemical oxidation of  $\text{Ni}^{\text{II}}\text{L}^{2+}$  in aerated solutions containing ATP, results in an electrochemical irreversible process. This suggests that another plausible role of ATP in biological systems is the stabilization of high valent transition metal complexes.
